Information for haemodialysis patients: Why have a fistula?

There are three principal forms of vascular access available for patients having regular haemodialysis, they are: Fistula, Graft or a Central Venous Catheter.

The Renal Association have recommended which of these are the most preferable:

- As first choice they recommend a fistula (also known as arteriovenous fistula or AVF)
- As second choice they recommend a graft (also known as arteriovenous graft or AVG)
- As third choice they recommend a catheter placed in a central vein (sometimes referred to as a neckline, central line or CVC)

The reason they recommend a fistula as first choice is that many studies have shown the superiority of fistulas compared to the other forms of venous access for haemodialysis.

Fistulas have better patency rates, they last longer, they need less additional interventions during their entire life span and have a lower rate of access related infection. The overall benefits of a fistula are better than having a graft or a catheter placed into a central vein. In addition, there are less hospital admissions with a fistula, compared to having a central venous catheter.

Frequently asked questions – All patients

“Why should I have a fistula?”

A fistula has been suggested because it is the best and safest option for you. You will have less risk of infection and other serious complications with a fistula compared to a line. A fistula will also facilitate better, more effective dialysis which is essential for your long-term health and quality of life.

“What does having a fistula involve?”

A fistula is made in the lower or upper arm by a small operation to connect an artery to a vein, usually done under local anaesthetic. It is created by a surgeon in an operating theatre and takes around 1 hour.

If the procedure is going to be more complex, then you may need a general anaesthetic (so you will be asleep). The surgeon will explain this to you prior to the procedure.

Patient Information leaflet for: Why have a fistula?

“I’m worried about the operation and what happens afterwards.”

A fistula formation procedure is usually very straightforward and is usually done as a day case. Before you go home you will be given advice on how to care for and monitor your fistula and details of who to contact if you have any problems/queries. The nurses on your dialysis unit will also monitor your fistula. There are also dialysis access nurse specialists (DANS) based at the Norfolk and Norwich Kidney Centre (NNKC) - contact details are at the end of this leaflet.

“I’m worried a fistula will change the way I look.”

Fistulas can change their appearance over time, however good needling technique can help to reduce the potential for aneurysms forming – these are the swellings or ‘lumps’ that can be seen in some fistulas. You can discuss your concerns with your nurses.

“I’m worried the fistula won’t work.”

In all cases we take every step to make sure that your fistula will work properly by carrying out an ultrasound scan of your veins and arteries before your fistula formation. This is to ensure that we are using the best blood vessels for your surgery. Despite this, the fistula may not mature adequately in a small number of patients. In these circumstances, you will be referred back to the surgeon for further assessment.

“I’m scared of needles and worried that using my fistula will hurt.”

We understand that people are concerned about the use of needles and there are ways that we can help with this. There are creams and sprays that can help to numb the skin if necessary, your dialysis nurses can explain these to you. Some patients seek counselling via their GP to help with their anxiety about needles. Once the fistula is established then there is a cannulation technique called 'buttonhole cannulation' which involves inserting blunt needles into a formed track. Patients usually find this less painful and so this can be a good option for people who are afraid of needles. Your nurses can explain this to you in greater detail.

Frequently asked questions - for patients who are already on dialysis via a central venous catheter

“My line works just fine, and I’ve never had an infection before, so why should I change?”

Even if you’ve never had an infection in your line, there is always a higher risk of future infections compared to a fistula. The longer you continue to dialyse with a line, the greater the risk of infection. Lines are also very prone to becoming blocked and may need to be replaced. Due to the vein narrowing caused by lines, the longer a line is in place, the more limited a person’s options for future vascular access becomes (eg; a fistula).

“Why can’t I wait to have a fistula until my line stops working?”

Unfortunately it takes 6-8 weeks for a fistula to be ready for use. If your line stops working or gets infected and has to be removed, this could leave you without any access for dialysis.

“I feel in control with my line. Isn’t it my decision?”

Yes it is your decision. However, a fistula would give you as much, if not more, control in managing your treatment and open options to you such as home haemodialysis (if you are a suitable candidate for this) and self-cannulation. You are also able to shower, bath and go swimming with a fistula.

“I’ve seen other people have problems with their fistula.”

Every person and every fistula is different. Sometimes people do have difficulties with their fistula being needed. These problems are usually temporary and there are things we can do to rectify these situations.

Further Information:

We appreciate that you may have your own questions and concerns about your decision and we are happy to discuss these with you.

If you would like any further information please speak with you renal doctor in clinic, the dialysis nurses or the Dialysis Access Nurse Specialists who are based at the Norfolk and Norwich Kidney Centre, 1-4 Francis Way, Bowthorpe, Norwich NR5 9JA.
